

Chapter 6: Content Framework

Overview

Chapter 6 (pp. 111–126) of *Mastering the TOGAF® Standard* introduces the **Content Framework**, the categorization mechanism the TOGAF Standard uses to structure the work products, models, and deliverables produced across the Architecture Development Method (ADM). The chapter explains why the Content Framework exists (consistency, coherence, gap reduction, standardized vocabulary), walks through its basic six-section structure and how that structure maps one-to-one onto the ADM phases, introduces the more granular **Extended Content Framework** (which maps individual entities from the Enterprise Metamodel onto ADM phases), and closes by explaining how and when the Content Framework and Enterprise Metamodel may be tailored/updated as an architecture project proceeds. The chapter is short (16 printed pages) but dense, and is part of the book's "GREEN and GOLD" reading tours (p. 111).

Detailed Section Breakdown

Introduction (pp. 111)

The Content Framework is introduced as best understood as a **categorization framework**. Its primary purpose is to structure the work products and models that make up the architecture and to describe the architecture products used in an organization. It promotes consistency and coherence in the deliverables produced across the phases of the ADM. In its **extended form**, it also provides a comprehensive checklist of architecture deliverables, reducing the risk of gaps in final architecture deliverables. In short, it helps an organization use standard architecture concepts, terms, and deliverables.

6.1 A Categorization Framework (pp. 111–114)

This section grounds the Content Framework in the ADM. The ADM provides a way to develop and manage architectures within an organization; it consists of **eight main phases** and is preceded by a **Preliminary Phase**. Central to the ADM is **Requirements Management** — this is **not** a separate phase, but rather a mechanism for continuously testing the architecture against requirements throughout the cycle. Every ADM phase (except Requirements Management) describes a set of architecture work products.

The author stresses that because organizations differ, the TOGAF Standard should always be **tailored** to the requirements and needs of the specific organization so the framework fits its type and way of working.

One of the first steps in establishing the Architecture Capability (covered further in Chapter 9) is defining, during the **Preliminary Phase**, three essential things:

1. **An Understanding of the Types of Entities** — understanding the entity types used in the organization and the relationships between them; this is captured formally by the **Enterprise Metamodel**.
2. **A Categorization Framework** — needed to structure architecture descriptions, the work products used to express an architecture, and the collection of models describing the architecture; this categorization framework **is** the Content Framework.
3. **The Specific Artifacts** — once the metamodel's entities and the categorization framework exist, the specific artifacts to be developed can be determined.

The Content Framework and the Enterprise Metamodel are closely related but distinct: the **Enterprise Metamodel** is a **detailed** representation of the entities that exist in the organization, while the **Content Framework** is a **high-level summarization** — hence "categorization framework" is described as the more fitting term. The Content Framework's content is a collection of models representing the architecture, and its categorization mechanism can be used to structure a representation of the Enterprise Metamodel.

Per reference [11], the Content Framework is intended to (this is a five-item enumerated list spanning pp. 113–114 and is highly quotable/testable):

- **Describe a detailed model** of the architecture products used in an organization (models may differ per organization, hence the need for tailoring).
- **Promote consistency and coherence** in the deliverables produced by following the ADM phases — the same entities are always used and always mean the same thing.

- **Provide a comprehensive checklist** of architecture deliverables that can be produced — a checklist can be created per category of entities specifying which deliverables can/should be produced.
- **Reduce the risk of gaps** in the final architecture deliverables — because it is predetermined which models use which entities, gaps are minimized (provided the Content Framework is carefully filled out beforehand).
- **Help an organization use standards** such as architecture concepts, terms, and deliverables — predefined entities within Content Framework categories remove ambiguity; each entity has a definition, prescribed terminology, and defined deployment within architecture deliverables.

The section closes by calling the Content Framework a well-thought-out categorization mechanism that seamlessly connects to the ADM phases, making it a very valuable addition to the TOGAF Standard.

6.2 Advantages of the Content Framework (pp. 114–117)

This section covers why the Content Framework is beneficial. It is central to defining and organizing architectural work products throughout the architecture development process, and is designed to provide a more modern, flexible, outcome-driven approach to Enterprise Architecture. Per reference [11], it defines a categorization framework used to structure the architecture description, the work product used to express an architecture, and the collection of models describing the architecture.

The chapter enumerates the Content Framework's **key aspects** (a heavily testable list spanning pp. 115–117):

- **Modular Structure** (p. 115): The TOGAF Standard is more modular than previous versions, letting organizations adopt only the relevant parts of the framework; this modularity extends to the Content Framework.
- **Core Content Model** (p. 115): The Content Framework provides a comprehensive content model (**Figure 6-1**) defining the types of building blocks and artifacts an architecture effort should produce — core concepts such as actors, processes, applications, data entities, and technology components. This ensures consistency across the Business, Data, Application, and Technology architectural views.
- **Extended Content Model** (p. 115): The framework also allows for extended content models providing additional depth in specific areas such as security, governance, or data management — making it easier to tailor the framework to organizational context. *(Note: this "Extended

Content Model" concept is distinct from the "Extended Content Framework" introduced later in Section 6.3/Figure 6-2 — a distinction worth knowing for exam purposes.)*

- **Architecture Artifacts** (p. 116): The Content Framework defines key artifacts like **catalogs, matrices, and diagrams** to document different aspects of the architecture — examples given are a **Business Process Catalog** and an **Application Portfolio Matrix**. These artifacts align with ADM phases.
- **Views and Viewpoints** (p. 116): The framework emphasizes creating views and viewpoints — views are ways of looking at the architecture to address different stakeholders' concerns; viewpoints define the conventions for constructing and using the views, ensuring consistency and relevance.
- **Alignment with Agile and Digital Transformation** (p. 116): TOGAF places stronger emphasis on supporting agile methodologies and digital transformation; the Content Framework is designed for use alongside modern practices like DevOps and cloud architecture.
- **Guidance for Tailoring** (p. 116): TOGAF includes extensive guidance on tailoring the metamodel and artifacts to specific organizational needs. Tailoring is done by **selecting, adapting, and using** those parts of the framework valuable to the situation/organization; it establishes a set of tools and a common vocabulary.
- **Outcome-Focused** (p. 117): A major shift versus earlier TOGAF versions is the focus on **outcomes rather than just processes**. The Content Framework reflects this by emphasizing creation of valuable architecture artifacts that deliver business outcomes rather than just following a rigid structure.

The section closes (p. 117) by summarizing that the Content Framework differs from previous versions in **flexibility, integration, and emphasis on outcomes** — it is more flexible due to modularity/adaptability, integrates better with other frameworks/methodologies (e.g., agile), and focuses more strongly on actionable outputs contributing to business objectives.

6.3 Mapping to the Architecture Development Method (pp. 117–123)

This section shows how the Content Framework maps to the ADM, both at a high level (basic Content Framework, **Figure 6-1**) and in fine-grained entity detail (**Extended Content Framework, Figure 6-2**).

Figure 6-1 (p. 118), "The Content Framework by ADM phase," illustrates that the Content Framework consists of **six sections** (an important enumerated/testable list, pp. 117–119):

4. **Architecture Principles, Vision, Motivation, and Requirements** — captures the surrounding context of formal architecture models: general Architecture Principles, strategic context feeding architecture modeling, and requirements generated from the architecture. Relevant business-context aspects that gave rise to the Request for Architecture Work are typically recorded during the **Preliminary** and **Architecture Vision** phases.
5. **Business Architecture** — captures architecture models of the business: factors that motivate the organization, its structure, and its capabilities. Aligns with **Phase B (Business Architecture)**.
6. **Information Systems Architectures** — captures architecture models of applications and data; uses the Information Systems Architectures phase, i.e., **Phase C**.
7. **Technology Architecture** — captures technology assets used to implement/realize information system solutions; realized via **Phase D (Technology Architecture)**.
8. **Architecture Realization** — captures change roadmaps showing the transition between architecture states, used to guide/drive implementation; aligns with **Phase F (Migration Planning)** and **Phase G (Implementation Governance)**.
9. **Architecture Change Management** — captures internal/external events affecting the Enterprise Architecture that generate action requirements; provided by **Phase H** of the ADM.

The Content Framework is meant to complement the ADM by describing what the architecture should look like once complete (p. 119).

Figure 6-2 (p. 120), "The Extended Content Framework," is the more detailed model. It contains the entities to be used/applied, plus their relationship to ADM phases, and its entities are **derived from the Enterprise Metamodel** (detailed in Chapter 5). Walking through its layout (pp. 120–122):

- **Preliminary** (top-left, part of the top layer "Architecture Principles, Vision, and Requirements") — shows development of **Architecture Principles** unfolding in this phase (though more happens in the Preliminary Phase than this narrow focus suggests).
- **Architecture Requirements** (to the right of Preliminary, same top layer) — contains the entities **requirements, constraints, assumptions, gaps, and locations** — most of the "General Entities."
- **Architecture Definition** (directly below the top layer) — the section containing by far the most entities. It is divided into **Motivation, Business Architecture, Information Systems Architectures, and Technology Architecture**, with the latter three naturally relating to **Phases B, C, and D**.

- **Motivation** is called out as an inconsistency (p. 121, boxed note): it contains the **driver, goal, objective, and measure** entities, which, according to the Enterprise Metamodel, actually belong to the Business Architecture section. One would expect them to be part of Business Architecture in the Extended Content Framework, but TOGAF has not done so for unexplained reasons. The author

speculates this may stem from a desire to emphasize entity/element coherence during development, combined with many different contributors working on the Standard.

- **Business Architecture** consists of **19 entities**, all described in **Chapter 5, Section 5.1.2** (p. 122).
- **Information Systems Architectures** (Data and Application Architecture) entities are covered in **Chapter 5, Sections 5.1.3 and 5.1.4**.
- **Technology Architecture** entities are covered in **Chapter 5, Section 5.1.5**.
- **Architecture Realization** (final section) consists of two parts:
 - **Opportunities, Solutions, and Migration Planning** — has a one-to-one relationship with **Phases E and F** of the ADM. Its entities, **capabilities** and **work packages**, are part of the General Entities in the Enterprise Metamodel (alongside requirements, constraints, assumptions, gaps, locations).
 - **Implementation Governance** — named for and associated with the ADM phase of the same name (**Phase G**). As an exception to the rule, its entities (**standards, guidelines, and specifications**) are **not** found in the Enterprise Metamodel — they are instead taken from the **Architecture Repository** (see Chapter 7).
- **Architecture Change Management** — related to **Phase H**, positioned on the right-hand side of the Extended Content Framework, running top to bottom.

The section closes (p. 122) by emphasizing that the Content Framework and Extended Content Framework are directly related to the ADM phases, cleverly showing that the schematic representation of an architectural approach relates seamlessly to its well-known implementation approach, the ADM.

6.4 Tailoring the Content Framework (pp. 123–125)

Referencing Chapter 5, Section 5.2, this section explains that the ADM can update the Content Framework and Enterprise Metamodel, but only under specific circumstances. While the Content Framework is a set of reference materials, the ADM's iterative nature allows architecture content to be updated/refined as the project progresses, specifically during (an enumerated, testable list, p. 123):

- **Phase A (Architecture Vision):** Initial architecture content is established and aligned with business objectives; this phase may identify the need for additional content or specific viewpoints not originally part of the Content Framework.

- **Phases B, C, and D (Business, Information Systems, and Technology Architectures):** As detailed architectures are developed, the specific architecture artifacts created may add to or modify existing Content Framework components.
- **Phase H (Architecture Change Management):** Explicitly designed to manage architecture changes, which may necessitate updates to the Content Framework reflecting new/modified standards, models, or deliverables.
- **Throughout the Architecture Development Cycle:** New insights, stakeholder feedback, or newly identified architectural requirements may drive changes/additions to both the Content Framework and the Enterprise Metamodel.

A worked example (pp. 123–124): during **Phase F**, it is recommended that a roadmap be created including all activities required to implement the architecture work; in TOGAF terms these activities are called **initiatives or work packages**. A boxed note (p. 124) points out that although both the Content Framework and Enterprise Metamodel reference the **work package** entity, TOGAF doesn't otherwise use this entity except in the **Project Context Diagram** artifact (see Chapter 12, Section 12.8.2, Figure 12-41). The author therefore **recommends** adding an additional architecture artifact to the Content Framework: the **Work Package Portfolio Map** (see Chapter 14, Section 14.8), and including it in the model shown in Figure 7-13 (Chapter 7, Section 7.5.1).

The Work Package Portfolio Map is especially useful during **Phase E (Opportunities and Solutions)** and **Phase F (Migration Planning)** (p. 124): it contains all the initiatives (work packages) needed to perform the architecture work, and illustrates the relationships between initiatives and organizational goals/objectives. It is therefore described as an essential artifact for establishing the relationship between the organization's business goals and their planning via the **Architecture Roadmap**.

The section closes (pp. 124–125) noting that while the Enterprise Metamodel and Content Framework serve as a guide, the iterative execution of the ADM ensures they evolve and are refined as part of overall architecture governance and development. A **Further Reading** box (p. 125) points to **"The TOGAF® Leader's Guide to Establishing and Evolving an EA Capability,"* Chapter 8, "Customization of Architecture Contents and Metamodel," document number G184.*

6.5 Summary (pp. 125–126)

The chapter's summary restates its core points: the Content Framework is a categorization framework used to make sense of architecture descriptions and to place/clarify entity types in the

context of the ADM; it is a **one-to-one translation of the ADM phases**. In addition to the compact form, there is the more extensive **Extended Content Framework**, in which all entities used in architecture work are mapped to ADM phases, derived from the Enterprise Metamodel.

The Content Framework aims to be adaptable across organizational contexts while comprehensively covering relevant architecture elements. It is more modular than previous versions (hence more adaptable); it defines key artifacts (catalogs, matrices, diagrams) to document architecture aspects; it emphasizes views and viewpoints; and it places stronger emphasis on supporting agile methodologies and digital transformation. A major shift versus earlier TOGAF versions is its **focus on outcomes rather than just processes**, emphasizing valuable architecture artifacts that deliver business outcomes rather than rigid structure-following. Overall, the Content Framework differs from previous versions in **flexibility, integration, and emphasis on outcomes**.

Key Terms & Definitions

- **Content Framework** (p. 111) — Best thought of as a categorization framework; its primary purpose is to structure the work products and models that make up the architecture and to describe the architecture products used in an organization.
- **Requirements Management** (p. 111) — Not a separate ADM phase, but a mechanism for continuously testing the architecture against requirements; central to the ADM.
- **Enterprise Metamodel** (p. 112) — A formal model representing the types of entities used in an organization and the relationships between them; a *detailed* representation of the entities that exist in the organization (contrast with Content Framework's high-level summarization).
- **Categorization Framework** (p. 112) — The mechanism needed to structure architecture descriptions, the work products used to express an architecture, and the collection of models describing the architecture; described as a more fitting term for the Content Framework.
- **Core Content Model** (p. 115) — The comprehensive content model (Figure 6-1) defining the types of building blocks and artifacts an architecture effort should produce (actors, processes, applications, data entities, technology components), ensuring consistency across Business, Data, Application, and Technology views.
- **Extended Content Model** (p. 115) — Provides additional depth in specific areas (e.g., security, governance, data management), letting architects tailor the framework to organizational context. (Distinct from the "Extended Content Framework," p. 120.)

- **Architecture Artifacts** (p. 116) — Key artifacts defined by the Content Framework: catalogs, matrices, and diagrams (e.g., Business Process Catalog, Application Portfolio Matrix), designed to align with ADM phases.
- **Views / Viewpoints** (p. 116) — Views are ways of looking at the architecture to address different stakeholders' concerns; viewpoints define the conventions for constructing and using the views.
- **Tailoring** (p. 116) — Done by selecting, adapting, and using those parts of the framework that are valuable to the situation or organization; establishes a set of tools and a common vocabulary.
- **Extended Content Framework** (p. 120) — The expanded model (Figure 6-2) containing the entities to be used/applied plus their relationship to ADM phases; entities are derived from the Enterprise Metamodel.
- **General Entities** (p. 121–122) — Entities not confined to a single architecture domain: requirements, constraints, assumptions, gaps, locations (Architecture Requirements section); also capabilities and work packages (Architecture Realization section).
- **Motivation (entities)** (p. 121) — Driver, goal, objective, and measure entities; per the Enterprise Metamodel these belong to Business Architecture, but the Extended Content Framework places them in their own "Motivation" section — flagged as an inconsistency in the Standard.
- **Work Package** (p. 123) — TOGAF's term for an activity performed in the context of implementing the architecture work (also called an "initiative").
- **Work Package Portfolio Map** (p. 124) — An artifact recommended by the author (not formally emphasized elsewhere in TOGAF) that contains all initiatives/work packages needed to perform architecture work and illustrates relationships between initiatives and organizational goals/objectives; useful in Phases E and F.
- **Architecture Repository** (p. 122) — Source of the standards, guidelines, and specifications entities used in the Implementation Governance section (an exception, since these are not part of the Enterprise Metamodel); detailed in Chapter 7.

Figures & Tables Referenced

- **Figure 6-1 — "The Content Framework by ADM phase"** (p. 118): Shows the (basic) Content Framework's six sections and how each maps onto ADM phases (Architecture Principles/Vision/Motivation/Requirements → Preliminary/Vision; Business Architecture → Phase B; Information Systems Architectures → Phase C; Technology Architecture → Phase D; Architecture Realization → Phases F & G; Architecture Change Management → Phase H). This is the high-level "Core Content Model" view referenced earlier on p. 115. Important because it is the master mental model connecting the Content Framework to the ADM.

- **Figure 6-2 — "The Extended Content Framework"** (p. 120): The detailed, entity-level version of Figure 6-1. Shows how individual entities (derived from the Enterprise Metamodel) are organized into Preliminary, Architecture Requirements, Architecture Definition (with Motivation, Business Architecture, Information Systems Architectures, Technology Architecture sub-sections), Architecture Realization (Opportunities/Solutions/Migration Planning + Implementation Governance), and Architecture Change Management — each tied to specific ADM phases. Important because it is likely to be tested on which entities live in which section and which section maps to which phase, plus the noted Motivation-section inconsistency.
- **Figure 1-1** (Chapter 1, Section 1.3 — referenced on p. 111, not shown in this chapter): The book's reading-tour diagram; Chapter 6 is flagged as part of the "GREEN and GOLD" reading tours.
- **Figure 12-41** (Chapter 12, Section 12.8.2 — referenced on p. 124, not shown in this chapter): The Project Context Diagram artifact, the only place TOGAF currently uses the "work package" entity.
- **Figure 7-13** (Chapter 7, Section 7.5.1 — referenced on p. 124, not shown in this chapter): A model the author suggests should also include the recommended Work Package Portfolio Map artifact.
- No numbered Tables appear in this chapter — content is conveyed via the two figures above plus extensive bulleted/enumerated lists in the body text.

Key Takeaways / Exam Focus Points

- The ADM consists of **8 main phases** preceded by a **Preliminary Phase; Requirements Management is a continuous mechanism, not a phase** (p. 111).
- Establishing an organization's Architecture Capability during the Preliminary Phase requires defining **3 things**: understanding of entity types (Enterprise Metamodel), a categorization framework (Content Framework), and the specific artifacts (p. 112).
- **Content Framework vs. Enterprise Metamodel**: Enterprise Metamodel = detailed entity representation; Content Framework = high-level categorization/summarization of the same (p. 112–113).
- The Content Framework is intended to do **5 things** per reference [11]: describe a detailed model of architecture products, promote consistency/coherence, provide a comprehensive checklist, reduce risk of gaps, and help standardize concepts/terms/deliverables (pp. 113–114).
- **Key aspects of the Content Framework (7 total)**: Modular Structure, Core Content Model, Extended Content Model, Architecture Artifacts, Views and Viewpoints, Alignment with Agile/Digital Transformation, Guidance for Tailoring, and Outcome-Focused — actually 8 bullets total across pp. 115–117 (Modular Structure, Core Content Model, Extended Content

Model, Architecture Artifacts, Views and Viewpoints, Alignment with Agile and Digital Transformation, Guidance for Tailoring, Outcome-Focused).

- **Extended Content Model ≠ Extended Content Framework** — easy to confuse. The former (p. 115) is about tailoring content depth (security, governance, data management); the latter (p. 120, Figure 6-2) is the full entity-to-ADM-phase mapping diagram.
- Architecture artifacts come in **3 types: catalogs, matrices, diagrams** — e.g., Business Process Catalog, Application Portfolio Matrix (p. 116).
- The (basic) Content Framework has **6 sections**, each mapped to specific ADM phase(s): Architecture Principles/Vision/Motivation/Requirements (Preliminary/Vision); Business Architecture (Phase B); Information Systems Architectures (Phase C); Technology Architecture (Phase D); Architecture Realization (Phases F & G); Architecture Change Management (Phase H) (pp. 117–119).
- The **Extended Content Framework's** entities are derived from the **Enterprise Metamodel** (Chapter 5) (p. 120).
- The **Business Architecture** section of the Extended Content Framework has **19 entities** (detailed in Chapter 5 §5.1.2); Data/Application entities in §5.1.3/5.1.4; Technology entities in §5.1.5 (p. 122).
- Known **inconsistency**: Motivation entities (driver, goal, objective, measure) belong to Business Architecture per the Enterprise Metamodel but sit in their own section in the Extended Content Framework (p. 121).
- **Architecture Realization** splits into two parts in the Extended Content Framework: "Opportunities, Solutions, and Migration Planning" (Phases E & F; entities = capabilities, work packages) and "Implementation Governance" (Phase G; entities = standards, guidelines, specifications — sourced from the **Architecture Repository**, not the Enterprise Metamodel — a noted exception) (p. 122).
- **Architecture Change Management** section = **Phase H** (p. 119, 122).
- Content Framework/Enterprise Metamodel updates happen during **4 circumstances**: Phase A, Phases B/C/D, Phase H, and "throughout the Architecture Development Cycle" (p. 123).
- The author's recommended (not standard) artifact, the **Work Package Portfolio Map**, is useful in **Phases E and F** and links initiatives/work packages to organizational goals/objectives via the **Architecture Roadmap** (p. 124).
- TOGAF's only current use of the "work package" entity is in the **Project Context Diagram** (Chapter 12, Fig. 12-41) (p. 124).
- Overall chapter thesis: the Content Framework differs from earlier TOGAF versions in **flexibility, integration, and emphasis on outcomes** (pp. 117, 126).

Self-Check Questions

Q: What is the primary purpose of the Content Framework, and how is it best described conceptually?

A: It is best thought of as a categorization framework; its primary purpose is to structure the work products and models that make up the architecture and describe the architecture products used in an organization, promoting consistency and coherence across ADM deliverables. (p. 111)

Q: What three things must be defined when establishing an organization-specific Architecture Capability during the Preliminary Phase?

A: (1) An Understanding of the Types of Entities (formalized by the Enterprise Metamodel), (2) A Categorization Framework (i.e., the Content Framework), and (3) The Specific Artifacts to be developed. (p. 112)

Q: How does the Enterprise Metamodel differ from the Content Framework?

A: The Enterprise Metamodel is a detailed representation of the entities that exist in the organization; the Content Framework is a high-level summarization/categorization of that same information — "categorization framework" is the more fitting term for it. (p. 112–113)

Q: List the five things the Content Framework is intended to do, per reference [11].

A: Describe a detailed model of architecture products; promote consistency and coherence in ADM deliverables; provide a comprehensive checklist of architecture deliverables; reduce the risk of gaps in final architecture deliverables; and help an organization use standard architecture concepts, terms, and deliverables. (pp. 113–114)

Q: What is the difference between the "Core Content Model" and the "Extended Content Model"?

A: The Core Content Model (Figure 6-1) defines the types of building blocks/artifacts an architecture effort should produce (actors, processes, applications, data entities, technology components) to ensure consistency across Business, Data, Application, and Technology views. The Extended Content Model allows additional depth in specific areas (security, governance, data management) to tailor the framework to organizational context. (p. 115)

Q: What three types of architecture artifacts does the Content Framework define, and what examples are given?

A: Catalogs, matrices, and diagrams; examples given are a Business Process Catalog and an Application Portfolio Matrix. (p. 116)

Q: What are the six sections of the (basic) Content Framework, and which ADM phase(s) does each align to?

A: Architecture Principles, Vision, Motivation, and Requirements (Preliminary/Architecture Vision phases); Business Architecture (Phase B); Information Systems Architectures (Phase C); Technology Architecture (Phase D); Architecture Realization (Phases F & G); Architecture Change Management (Phase H). (pp. 117–119)

Q: What is the Extended Content Framework, and what is it derived from?

A: It is the detailed model (Figure 6-2) containing the entities to be used/applied plus their relationship to ADM phases; its entities are derived from the Enterprise Metamodel (described in Chapter 5). (p. 120)

Q: What inconsistency does the author point out regarding the "Motivation" section of the Extended Content Framework?

A: The Motivation section contains driver, goal, objective, and measure entities, which per the Enterprise Metamodel belong to Business Architecture — yet TOGAF places them in a separate Motivation section without explanation, an acknowledged inconsistency in the Standard. (p. 121)

Q: How many entities make up the Business Architecture section, and where are they detailed?

A: 19 entities, detailed in Chapter 5, Section 5.1.2 (Data, Application, and Technology Architecture entities are covered in Sections 5.1.3, 5.1.4, and 5.1.5 respectively). (p. 122)

Q: Into what two parts does the Extended Content Framework's "Architecture Realization" section split, and what entities/phases belong to each?

A: "Opportunities, Solutions, and Migration Planning" (Phases E & F; entities: capabilities, work packages — part of the General Entities) and "Implementation Governance" (Phase G; entities: standards, guidelines, specifications — sourced from the Architecture Repository rather than the Enterprise Metamodel, an exception to the rule). (p. 122)

Q: What artifact does the author recommend adding to the Content Framework to better handle work packages, and in which phases is it most useful?

A: The Work Package Portfolio Map (detailed in Chapter 14, Section 14.8); it is most useful during Phase E (Opportunities and Solutions) and Phase F (Migration Planning), since it contains all initiatives/work packages and illustrates their relationship to organizational goals/objectives via the Architecture Roadmap. (p. 124)

Q: During which four circumstances can the Content Framework and Enterprise Metamodel be updated, per Section 6.4?

A: During Phase A (Architecture Vision); Phases B, C, and D (Business, Information Systems, and Technology Architectures); Phase H (Architecture Change Management); and throughout the Architecture Development Cycle generally (driven by new insights, stakeholder feedback, or new requirements). (p. 123)
